

ResQRide — Emergency Response Page Spec

Design & UX specification for the post-crash landing page

ResQRide Emergency Response Page

Reference screenshot of the emergency response page

Purpose: This is the page a bystander lands on after scanning the QR code on a rider's helmet following a crash. It must work instantly, under stress, for a stranger who has never seen it before.

1. Zero-scroll triage at the top

The two biggest, boldest buttons on the page are **“Call ambulance”** and **“Call emergency contact”** — nothing else competes for attention above them. A panicked bystander shouldn't have to think or scroll; the first thing they see is the first thing they need to do.

2. Medical info organized by “what changes treatment,” not alphabetically

Blood group and allergies come first, because a paramedic's first questions at the scene are exactly that. Prescriptions come after, since they matter more once the person is stabilized, not in the first 60 seconds.

3. One-tap actions everywhere, not just information

Every contact and every hospital has a direct call/navigate button next to it — the page acts, it doesn't just display. That's the difference between an “informational site” and an “emergency tool.”

4. Live status framing

A small **“Crash detected · location shared live”** strip ties the page back to the ResQRide helmet device that triggered it — this is what makes it feel like part of one connected system, not a static profile page someone could've built in Google Forms.

5. Verified-ID trust signal

A small checkmark badge (“Verified medical ID”) tells a stranger this data is real and current, not something anyone could fake or edit.

6. Timestamp, quietly

Something like “2 min ago” / “updated from helmet sensor” — small detail, but it answers the unspoken question: *is this still accurate right now?*

7. Calm color discipline

Red is used only for genuinely urgent elements (the ambulance button, allergy badges) — not decoratively. If everything were red, nothing would read as urgent. That restraint is what separates a demo that looks alarmed from one that looks trustworthy under pressure.

Page structure (top to bottom)

1. **Header strip:** “Crash detected · location shared live” (red/urgent background) + “Verified medical ID” badge + timestamp (“Updated from helmet sensor”)
2. **Primary actions:** Two large buttons side by side — “Call ambulance” (filled red) and “Call contact” (outlined/neutral)
3. **Critical medical info card:**
 - Blood group + Age (two-column)
 - Allergies (colored badge chips — red for severe, amber for moderate)
 - Current prescriptions (name, dosage, frequency)
4. **Emergency contacts card:** Name, relationship, one-tap call icon for each contact
5. **Nearby hospitals card:** Name, distance, open-hours status, one-tap navigate icon for each
6. **Footer note:** “Data shown only after a real crash trigger · updated from helmet”

Known polish fix

- The hospital row icon (building/cross icon) currently overlaps with the text line below it — needs spacing/padding correction so icon and text don’t collide.

Visual/tone notes

- Dark background throughout (near-black), high-contrast white/light-gray text
- Card-based layout, each section in its own rounded container with subtle border
- Red reserved strictly for: crash-detected header, ambulance button, and severe-allergy badges
- Everything else neutral dark gray / white — calm, clinical, not alarming
- Rounded call/navigate action buttons (circular icon buttons) on the right edge of each list row
